

Head-Driven Phrase Structure Grammar

A natural language is described by

- universal principles
- language-specific principles
- the lexicon of the language
- the rules of the language

Principles of universal grammar: P_1, \dots, P_m

Head Feature Principle, Subcategorization Principle, Semantics Principle, ...

Principles of German: P_{m+1}, \dots, P_n

Constituent-Order Principle, ...

Lexicon of German: L_1, \dots, L_p

Rules of German: R_1, \dots, R_q

German = $P_1 \wedge \dots \wedge P_n \wedge (L_1 \vee \dots \vee L_p \vee R_1 \vee \dots \vee R_q)$

Subcategorization in HPSG

Rule: (subcat Rest) → (subcat [Comp|Rest]) , Comp

Lexicon: (subcat [NP(acc), NP(nom)]) → helps

NP → Peter

NP → Mary

Compositional Semantics

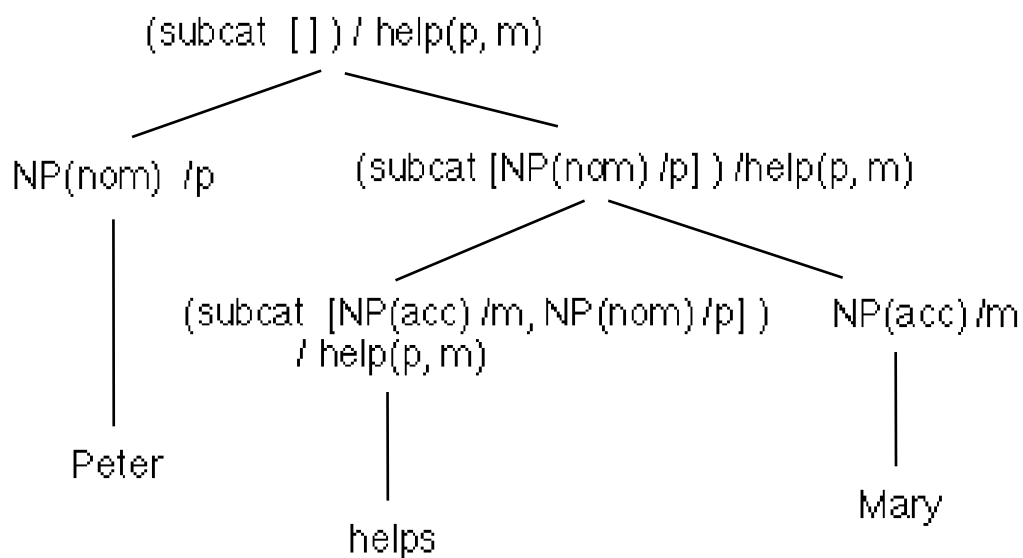

- Tradition of Richard Montague
- (almost) every constituent has a semantics

The semantics of a constituent is composed of the semantic of its daughter constituents

⇒ **Principle of composition**

- Use of different theories of semantics possible
(extensions to FOPL are common; ⇒ **logical form**)

Integration of Syntax and Semantics

Rule (format in Definite Clause Grammar):

<Syntax> / <Semantik>

(subcat [Rest]) /Sem → (subcat [Comp|Rest]) /Sem , Comp

Lexikon:

(subcat [NP(acc) /Obj, NP(nom) /Subj]) /help(Subj, Obj) → helps

NP/p → Peter

NP/m → Mary

Feature Structures in Matrix Form

$$\left[\begin{array}{l} \text{LHS} \left[\begin{array}{l} \text{SUBCAT} \boxed{2} \end{array} \right] \\ \text{HEAD-DTR} \left[\begin{array}{l} \text{SUBCAT} \langle \boxed{1}, \boxed{2} \rangle \end{array} \right] \\ \text{COMP-DTR} \boxed{1} \end{array} \right]$$

(subcat REST) → (subcat [COMP | REST]), COMP

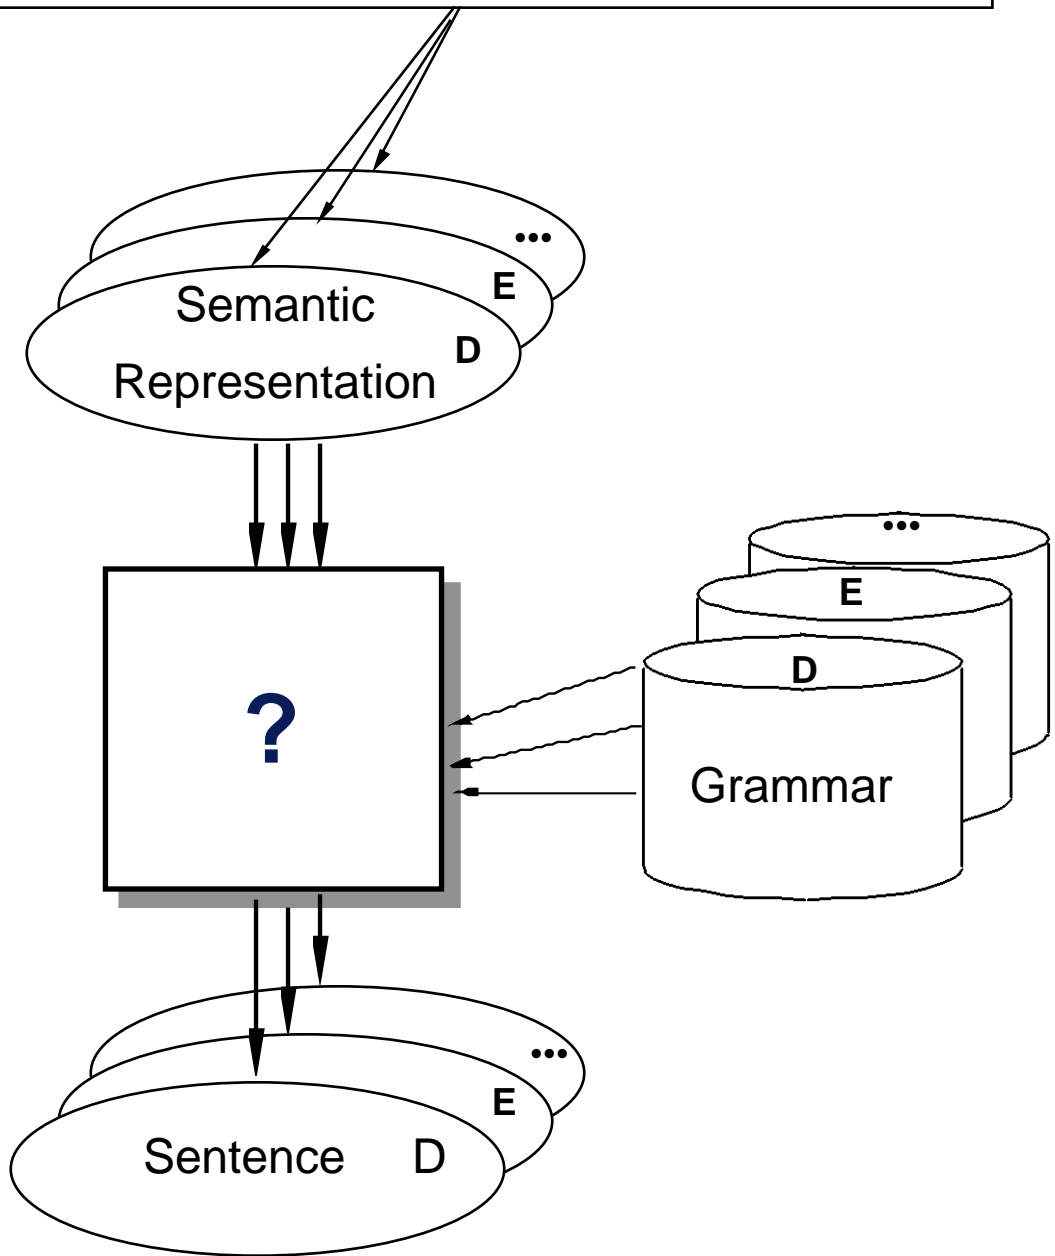

$$\left[\begin{array}{l} \text{LHS} \left[\begin{array}{l} \text{SUBCAT} \boxed{2} \\ \text{SEM} \boxed{3} \end{array} \right] \\ \text{HEAD-DTR} \left[\begin{array}{l} \text{SUBCAT} \langle \boxed{1}, \boxed{2} \rangle \\ \text{SEM} \boxed{3} \end{array} \right] \\ \text{COMP-DTR} \boxed{1} \end{array} \right]$$

(subcat REST) / SEM → (subcat [COMP | REST] / SEM, COMP

$$\left[\begin{array}{l} \text{LHS} \left[\begin{array}{l} \text{SUBCAT} \left\langle \left[\begin{array}{l} \text{CAT} \text{ np} \\ \text{CASE} \text{ acc} \\ \text{SEM} \boxed{1} \end{array} \right], \left[\begin{array}{l} \text{CAT} \text{ np} \\ \text{CASE} \text{ nom} \\ \text{SEM} \boxed{2} \end{array} \right] \right\rangle \\ \text{SEM} \left[\begin{array}{l} \text{PRED} \text{ help} \\ \text{ARG1} \boxed{2} \\ \text{ARG2} \boxed{1} \end{array} \right] \end{array} \right] \\ \text{DTR} \left[\text{MORPH helps} \right] \end{array} \right]$$

(subcat [NP(acc) / OBJ, NP(nom) / SUBJ]
/ help(SUBJ, OBJ)) → [helps]

- Natural Language Dialogue Systems
- Systems for Machine Translation
- Text generation systems

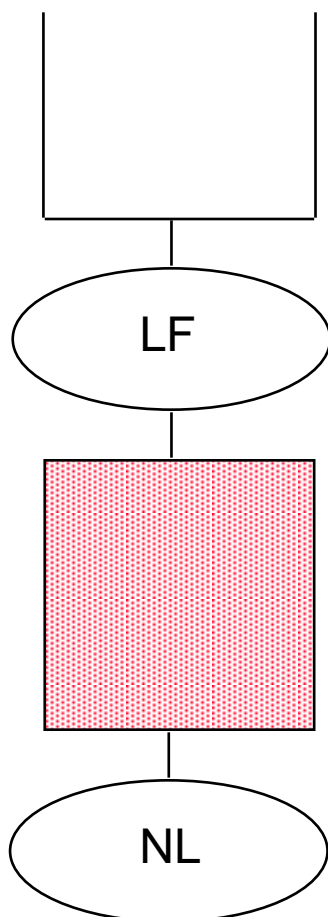

? = Efficient, multilingual generation with reversible grammars

Reversibility

- **Reversible grammars**

Parser and Generator use the same grammar

- **Reversible processes**

- Decision-making

- deduction-based

Shieber 1988, Neumann 1998

- type instantiation

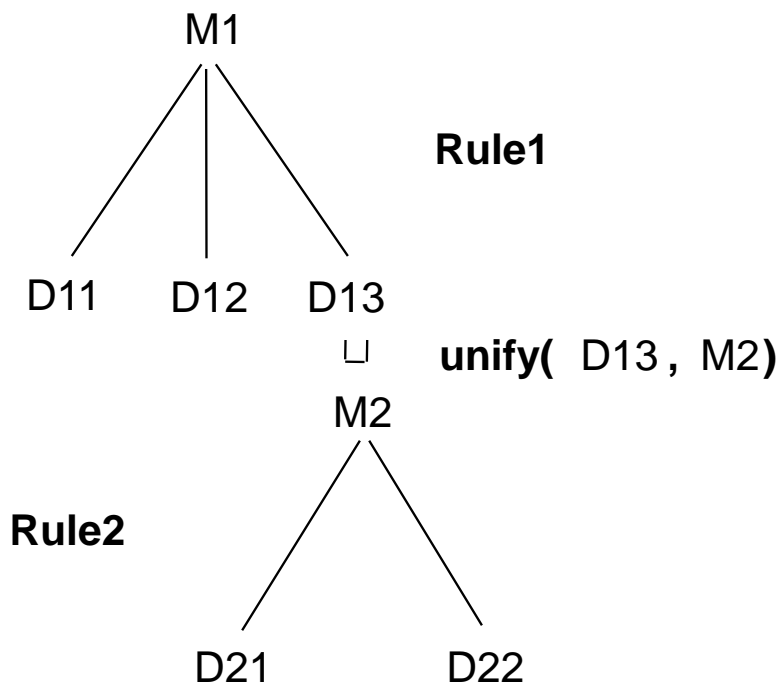

Emele/Zajac 1990

The Generation Task

- **Given a semantic representation and a grammar; which are the terminal strings admissible by the grammar?**
- Processing of syntax and formal semantics are at the focus of research
- Input is the semantic representation (logical form) of a sentence
- This representation is language-specific, i.e. it differs between e.g. German and English

⇒ Task is **word order** and **word inflection**

Processing Steps for Unification

- **Bottom-Up Step**

- 1. current node M2
- 2. unification with D13
- 3. new current node from {D11, D12}

- **Top-Down Step**

- 1. current node D13
- 2. unification with M2
- 3. new current node from {D21, D22}

Top-Down Generation Using Structural Subcategorization

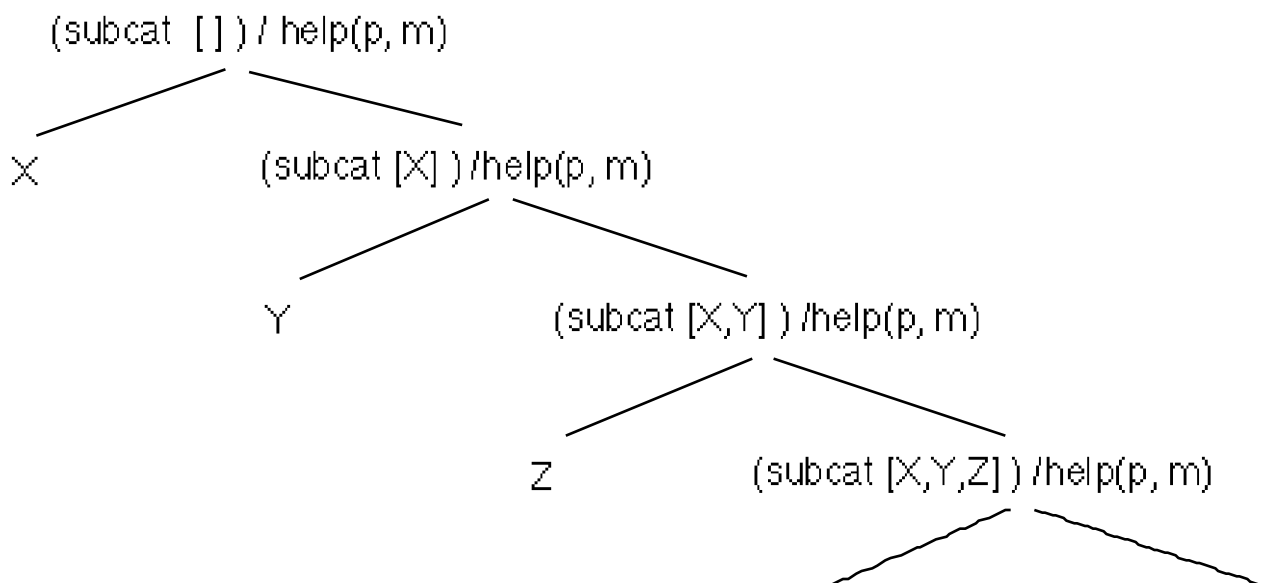

Input Structure:

(subcat []) /help(p, m)

Rule Application:

(subcat []) /help(p, m) \rightarrow (subcat [X]) /help(p, m), X

The same rule can be applied again to the result; the procedure does not terminate:

[Van Noord 1990]

Semantic-Head-Driven Generation: Pivot Nodes

- **Idea:** Strategy utilizing known information during generation, i.e. the semantics
- **Pivot:** deepest node in the derivation tree, such that this node and all nodes higher up in the path possess the same semantics
 - ⇒ *semantic head of the root node*
- **Generation** of derivation tree both top-down and bottom-up, starting from the respective pivots
 - ⇒ *semantic-head-driven*

SHDG algorithm

(following Shieber et al. 1990)

```
generate(Root) :-
    applicable_non_chain_rule(Root, Pivot, RHS),
    generate_rhs(RHS),
    connect(Pivot, Root).

generate_rhs([]).
generate_rhs([First|Rest]) :-
    generate(First),
    generate_rhs(Rest).

connect(Pivot, Root) :-
    applicable_chain_rule(Pivot, LHS, Root, RHS),
    generate_rhs(RHS),
    connect(LHS, Root).
connect(Pivot, Root) :-
    unify(Pivot, Root).

applicable_non_chain_rule(Root, Pivot, RHS) :-
    node_semantics(Root, Sem),
    node_semantics(Pivot, Sem),
    non_chain_rule(LHS, RHS),
    unify(Pivot, LHS).

applicable_chain_rule(Pivot, Parent, Root, RHS) :-
    chain_rule(Parent, RHS, SemHead),
    unify(Pivot, SemHead).
```

Semantic-Head-Driven Generation: Generating the Derivation Tree

Chain Rules form a subset of the grammar rules:

The semantics of one right-hand side element is identical to the semantics of the left-hand side

⇒ *semantic head of the rule*

Top-Down:

- Expansion of pivot using a Non-Chain Rule
- The daughters of a NCR are processed recursively
- Termination: There are no (more) nonterminal daughters, i.e. the NKR is a lexicon entry

Bottom-Up:

- Reduction of pivot towards the root using a Chain Rule
- The non-semantic-head daughters of a CR are processed recursively
- Termination: the pivot and the root nodes unify

Semantic-Head-Driven Generation: DCG sample grammar

sentence/decl(S) → s(finite) /S

s(Form)/S → Subj, vp(Form, [Subj]) /S

vp(Form, Subcat)/S → vp(Form, [Compl|Subcat]) /S, Compl

vp(finite, [np(_)/O, p/up, np(3-sing) /S]) /call_up(S,O) → [calls]

np(3-sing)/john → [john]

np(3-pl) /friends → [friends]

p/up → [up]

Input structure to SHDG procedure:

decl(call_up(john, friends))

Example (1)

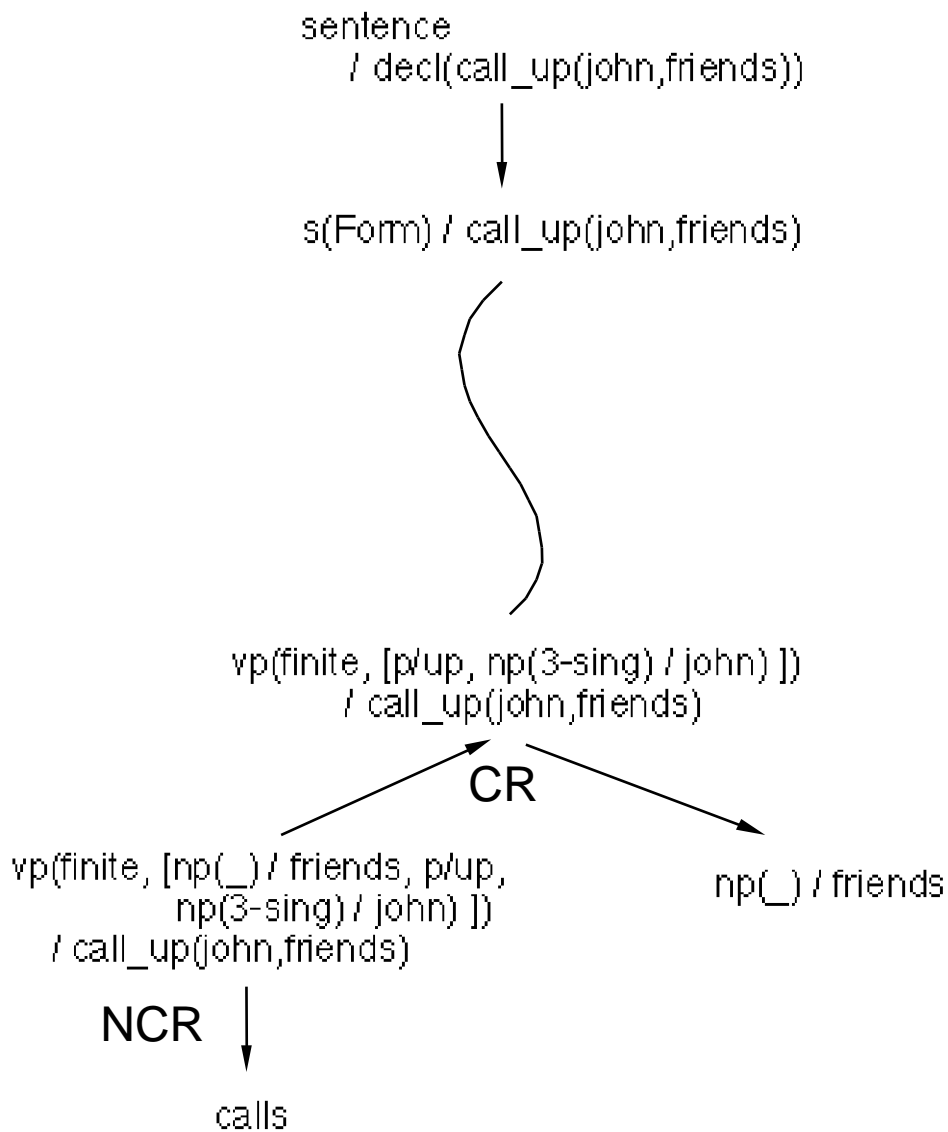

Pivot:

sentence
/ decl(call_up(john, friends))
↓
NCR
s(Form) / call_up(john, friends)

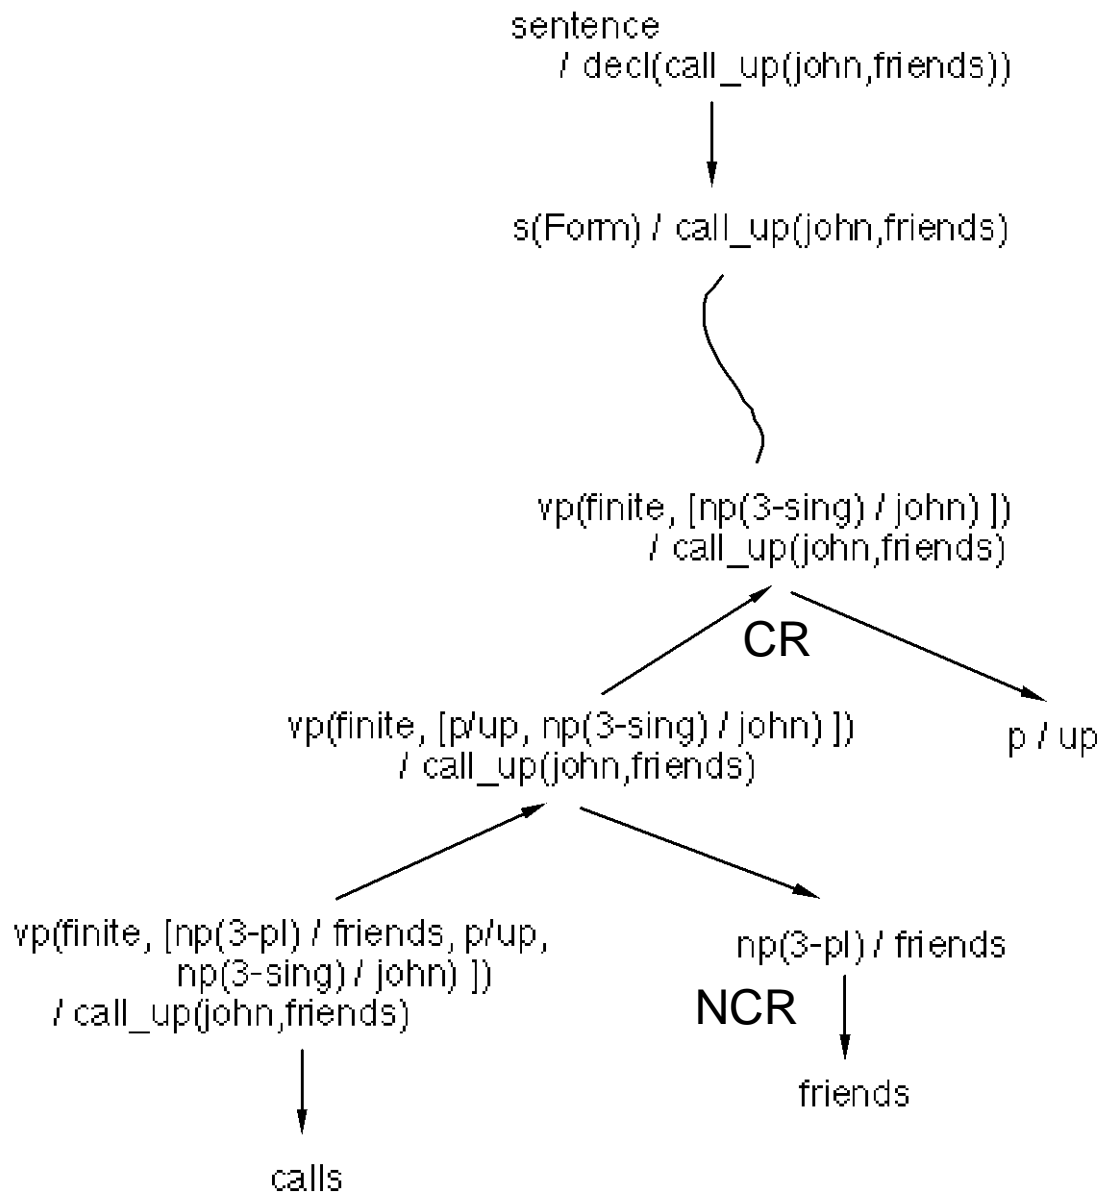

Pivot:

vp(finite, [np(_) / friends, p/up, np(3-sing) / john])
/ call_up(john, friends)
↓
NCR
calls

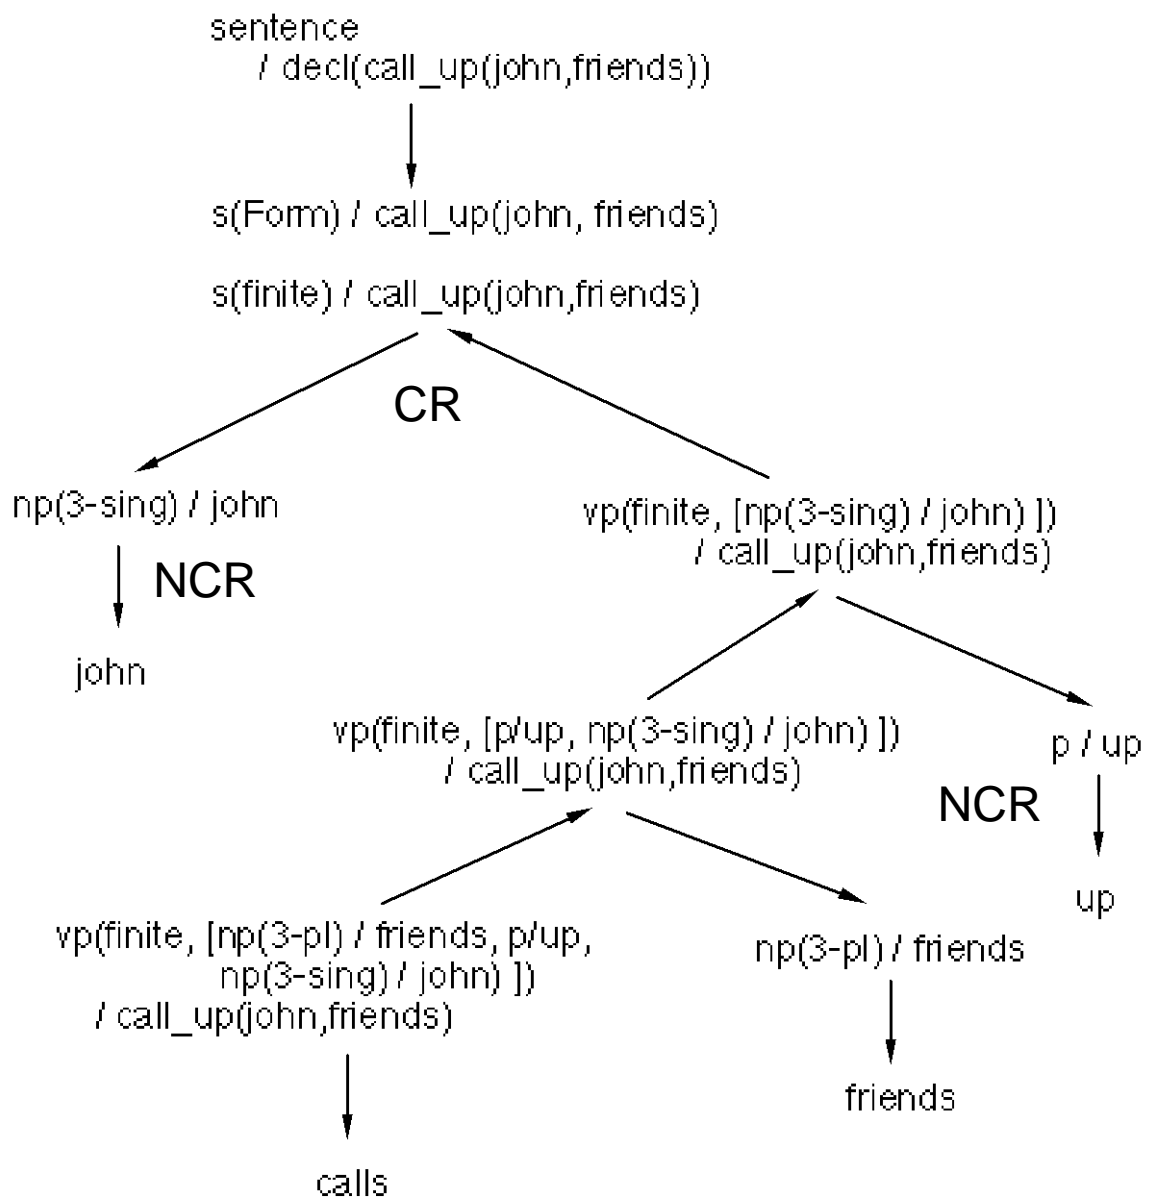

Example (2)

Example (3)

Example (4)

Logical Form (LF)

- There is no agreement on
 - which information *must* be represented in a LF
 - whether a LF must correspond to *exactly one* terminal string
- Grammars cannot derive unique LF from sentences; thus "ambiguous" *quasi-logical forms*
- Disambiguation (of anaphoric relations and scopus ambiguities) during parsing through subsequent analysis steps
- for generation, a unique LF can be assumed
- Equivalence problem for LF:
 - $p \text{ and } q \Leftrightarrow q \text{ and } p \text{ ??}$
John fell and lost his conscience.
 - $p \Leftrightarrow p \text{ and } (q \text{ or } (\text{not } q)) \text{ ??}$
John lost his conscience, and Bruce Springsteen is the boss, or Bruce Springsteen is not the Boss.
- Open research problem: What is "intended equivalence"?

Appelt 1987

Alshawi/van Eick 1989
